Mark Maupin The real estate market is hotter than ever for those wishing to buy and it is a great time to hop in and float up before the bubble pops. With the recent problems in the economy, the pricing of homes across the nation have slid down, but are slowly beginning to rise. If you are new to real estate investing, you need to be very realistic about your earning expectations. Instead, the property will require maintenance and repairs. Therefore, do not expect to start making money over night with a rental property. With a property that the owner intends to flip, the profit will be realized as soon as the property sells. Do not just scan over the mortgage, make sure that you read everything on the mortgage contract which includes the fine print. It is important that you completely understand what is expected of you from your mortgage company. Doing so will help you to make wise choices regarding your loan. Find a realtor that is knowledgeable about the area in which you are looking for a home. One important tip when it comes to real estate is to check the history of the area to see if there have been any natural disasters in the past. This can hopefully save you from property damage or loss of life with your home choice. This mainly is a tactic to use when moving to a new and unfamiliar territory. Such occurrences as flooding, wildfires, hurricanes, tornadoes, and earthquakes tend to repeat in the same geographical areas. If this is your first experience as a home buyer, do not make the common mistake of failing to treat the process like you would any other shopping trip. Buying a home is much different than buying clothing or anything else, and prospective buyers must make a conscientious commitment to do their homework, follow through with the sale, and stand by their decision. Buying your first home can be a lot of fun. Just make sure the home will fit your needs now, and also your future needs. If you entertain a lot or plan to expand your family, you will need a bigger house. If you are concerned with privacy, you will want to find one that will give you that. Take the time to really decide what you are looking for. You should always check your options for down payment assistance. Any financial assistance could be a big help. Understanding the resale value of a home is a very important consideration when deciding on what you should purchase. Most people do not stay in one place their entire life, so knowing what to look for and how it can impact a future sale should have an impact on your home buying decision. The perfect home is out there somewhere. Utilize the many online sites and you will find that there are many more homes on the market than what you find in your local paper. With some time spent online looking through many different sites, you are sure to find the one that is perfect for you. An important aspect to consider when buying a house is the number of bedrooms. Each neighborhood was built in a family model in sight so it is easier and usually cheaper to find a bedroom house in an area where most of the houses have bedrooms. If the neighborhood usually has smaller houses, you will pay much more for the extra bedroom. As the government is subsidizing your home purchase, buying a home not only provides housing to you and your family, but it has tax advantages too. All of the property taxes and mortgage interest you pay on the property can be deducted from your gross income, which may significantly reduce your taxable income. Buyers who enjoy constant rush, night life and entertainment should consider buying a property in a larger metropolitan area. This way they can be near to the restaurants, entertainment and night life they enjoy. This decision will definitely come with sacrifices as in the major cities, properties are significantly smaller and real estate prices are skyrocketing. When buying a property one should look for one that has a stream or river bordering or going through an area of the property. Having an attractive section of water nearby can increase the value of ones property, especially if it connects to a larger body of water. Learn how to do some basic repairs yourself. A well prepared investor who plans to make a long term investment into a property would be very wise to consider attending some classes on basic maintenance and repair. While it may seem easier to hire a handyman at first, the costs of small repairs will add up over time. Therefore, an owner who does small repairs will save more of their earnings in the long run. Take the time necessary to learn about property valuation in the areas where you

would consider purchasing an investment property. Always do your homework and get a market analysis through your real estate agent for any property in which you are interested. There are first time investors who have generated substantial income simply based upon the fact that they know how to determine true market value. By following through with some of the tips listed, you can learn how and where to purchase an affordable home that is priced far below its actual value. You can use this time to get it into the best shape ever and in a short time period sell it for massive gains.

He published various tests, to better understand if the project would be tasted, and to request relief enlightened, and finally did appear, after twenty years of work and research, a description of Lorraine and Barrois, who was regarded, with good reason, as a model works like this. He was then clerk of the State Council of Stanislas Leszczynski, and finally police lieutenant in Nancy. Durival was a member of the Academy of Nancy since 1775, and communicated to the company a lot of memories on objects of public utility. Place police lieutenant who was eliminated in 1775, he was appointed municipal administrator. Although he had served for most of his life gainful employment, he remained poor and he was included in the number of scholars that the Convention granted relief in 1793. Durival collaborated on the Encyclopedia of Diderot. He is the author of several books on the history, customs, agriculture, geography and customs of Lorraine.

For postage stamps, separation is the means by which individual stamps are made easily detachable from each other.. Methods of separation include: perforation: cutting rows and columns of small holes.

For this reason, only one significant figure at most is given before the exponent. A table of solubility products for many sulphides based on a reevaluated value for the second dissociation constant of H₂S is given in Ref. The values in that study are typically some orders of magnitude lower than the ones shown here. The values for oxides are not so readily available as for sulphides and selenides. However, it must also be kept in mind that deposition of oxides often occurs via a hydroxide or hydrated oxide, and therefore the relevant value is that of this hydroxide or hydrated oxide. This is due to the equilibrium between the two species: In this book, we will continue to use the more conventional solubility products, partly because they are more common and partly because the relevant equilibria are less unwieldy to describe. In applying the solubility product concept to CD, it is often useful to consider it in terms of what concentration of ions is required in solution before precipitation occurs. Thus, for CdS, with a K_{sp} value of ca. Thus a solution 0. K_{sp} can be derived theoretically from the free energies of formation of the species involved in the dissolution equilibria. This would be a case of supersaturation. In practice, however, the solubility product does give a fairly good idea of when precipitation will occur in most cases. Since almost all CD reactions are carried out in aqueous solutions, the pH of the deposition solution will give this concentration. The reason for this can be seen from Table 1. To prevent precipitation of metal hydroxides, a complexing agent often called a ligand, since complexing agents to cations are electron donors is added. The complexant also reduces the concentration of free metal ions, which helps to prevent rapid bulk precipitation of the desired product. This section gives the basics of the theory of complexation. If ammonium hydroxide ammonia in water is a common complexant for Cd in CD is added to a suspension of Cd(OH)₂, the Cd(OH)₂ will redissolve, assuming enough ammonia has been added. How much is enough ammonia? This can be calculated from the stability constant of the complex between ammonia and Cd. Add to this the ammonia tied up by complexation. At a Cd concentration of 0. The value of pH chosen is typical of these solutions. This calculation ignored the decrease in the stability constant of the complex with increasing temperature see later as well as the increase in K_{sp} that normally occurs with an increase in temperature. These two effects act in opposite directions; for most cases, their combined effect will be much smaller than that of the temperature-dependent ion product of water. Another simplification is the assumption of only one complex species; this simplification is reasonable for most purposes. If a solution contains an excess of one of the ions of a sparingly soluble salt, this will modify the solubility of the sparingly soluble salt according to the common ion effect. This effect is a general one, but the conclusions are not always valid; the example deliberately given here is one where it is not valid. The stability constant of a complex is temperature dependent increased temperature generally leads to increased dissociation of the complex. Qualitatively, this can be explained by the Le Chatelier principle, which states that if there is a change in a reaction parameter, the reaction will proceed in a direction that opposes that change. Thus an increase in temperature will cause the reaction to go in the direction in which heat is absorbed, which is dissociation of the complex. The derivation of this equation can be found in any elementary physical chemistry textbook and there is no need to repeat it here the result is what is important for us. This equation is approximate for a number of reasons. One is that it ignores changes in entropy that often will act in the opposite direction for complex formation. However, the trend is generally correct. The stability constant of a complex does not, according to Eq. The reason for this lies in the fact that the equilibrium shown in Eq. Since ammonia is a much stronger ligand than water water of hydration can be considered as a ligand, it will exchange all the water as long as the ammonia concentration is not too low. This color transition is reversible. The stronger the ligand relative to water, the less the concentration required to exchange the water. It is worth noting that a statistical effect different combinations of the various complexants may result in mixtures of complexants binding more strongly to a cation than would be expected based on the individual stability constants of the complexants [2]. If a compound containing more than one

cation is to be deposited, complexation could be used to offset the difference in K_{sp} between the individual metal compounds. As an example, consider the deposition of Cd,Hg S. This means that under the conditions of CD, where the sulphide ion is slowly formed, we would expect only HgS to form until almost all the Hg was used up. Some Cd might be incorporated into the deposit by adsorption, but the deposit should, according to considerations of solubility product, be predominantly HgS. The concentration of Hg in the deposit can be decreased by choosing a complex or mixture of complexes that complexes Hg more strongly than it does Cd. In this case, since Hg forms very strong complexes with many ligands, there is a large choice. In addition, the Hg concentration was much smaller than that of cyanide, while the Cd concentration was larger. This means that there was enough cyanide to complex the Hg but not enough for the Cd. This combination of factors allowed codeposition of the Cd and Hg as sulphides, but the concentrations of Hg in the films were larger by a factor of ca. This judicious use of a complexant to allow codeposition of two cations with widely differing values of K_{sp} is, unfortunately, not always useful. An example is the deposition of Cd,Zn S—a material of interest particularly because of its potential use in photovoltaic cells see Chapter 9. The stability constants of Cd and Zn ions are in most cases very similar for any particular complex although, of course, they vary greatly from one complex to another. Therefore complexation is very limited as a means to control the concentration of one of these ions relative to the other. The use of complexation to allow codeposition of alloys is well known in electroplating. There is a direct connection between this effect and the equivalent one for CD. This arises from the fact that, for both CD and electrodeposition of alloys we include mixed metal compounds in the term alloy, the effect of the complexant is to lower the concentration of free cations. For CD this affects the deposition through the solubility product, while for electrodeposition it affects the deposition potential through the Nernst equation: In the case of metal electrodeposition, the reduced species, Red, is the metal that, since it is a solid, can be taken as unity concentration. With this in mind, Eq. For this reason, we consider both types of nucleation. From another viewpoint, phase transformation occurs when the free energy of the new phase is lower than that of the initial metastable phase. However, there are many examples where the ion product exceeds K_{sp} , yet no precipitation occurs—the phenomenon of supersaturation. The solubility product also does not provide information on how the particles of the precipitate form—nucleation. Nucleation involves various physical processes, and both thermodynamic and kinetic aspects must be considered. Homogeneous nucleation can occur due to local fluctuations in the solution—whether in concentration, temperature, or other variables. The first stage in growth is collision between individual ions or molecules to form embryos embryos are nuclei that are intrinsically unstable against redissolution—see later. Embryos grow by collecting individual species that collide with them. While these species may be ions, atoms, or molecules in general, for CD, adsorption of ions on the embryo seems to be the most probable growth mechanism. They may also grow by collisions between embryos; however, unless the embryo concentration is large, this is less likely. These embryos may redissolve in the solution before they have a chance to grow into stable particles nuclei. Because of the high surface areas, and therefore high surface energies of such small nuclei, they are thermodynamically unstable against redissolution. They may, however, be kinetically stabilized by low temperatures, which increase their lifetime, possibly enough for them to grow to a size where they are thermodynamically stable. This results in an increase of the particle size, since there is more reactant per nucleus. The critical radius, R_c , is the size where the embryo nucleus has a The typical size of R_c is about molecules—between 1 and 2 nm in diameter. Solvent molecules can adsorb on the embryos and change their surface energy; the critical radius will therefore depend not only on the material of the nucleating phase but also on the solution phase. The energy required to form an interface between the FIG. The critical radius, R_c , depends on the balance between surface and volume energies of the growing particle. Therefore heterogeneous nucleation is energetically preferred over homogeneous nucleation and can occur near equilibrium saturation conditions, compared with the high degree of supersaturation often required for homogeneous nucleation. These subcritical nuclei can grow, either by surface diffusion or by material addition from solution. It should also be noted that nuclei that are subcritical in solution may be supercritical when adsorbed on a substrate. This is a consequence of reduced contact between nucleus and solution as well as stabilization of the adsorbed nucleus. These processes are shown schematically in Fig. It was noted earlier that even individual ions may

adsorb onto a surface. More specifically, depending on the surface chemistry of the substrate, individual ions or molecular species may actually be chemisorbed, creating a nucleus for reaction and further growth. Pure homogeneous nucleation is probably less common than might appear from the above discussion. Because of the greater ease of nucleation on a solid phase than homogeneously, any solid matter in the solution will act as a nucleation center. It is difficult to prepare solutions without some solid phase usually dust particles â€” careful filtering is necessary to attain such particle-free solutions. One is a continuation of the process of embryo growth discussed earlier: The next growth step will then be adsorption of the oppositely charged ion to give an additional CdS molecule. This process can continue until either all the ions of any one type are used up or growth is blocked, e. Also, growth may continue but in a different geometric orientation, giving rise to twinning, polycrystallinity, etc. Another mechanism for crystal growth is known as Ostwald ripening. If a small nucleus or embryo is close to a larger crystal, the ions formed by partial dissolution of the smaller, less stable crystal can be incorporated into the larger crystal. As the smaller crystal becomes even smaller, its dissolution will become ever more favorable and eventually it will disappear. The result is that the larger crystals grow at the expense of the smaller ones. If the concentration of particles is sufficiently high, then the probability of collisions between these particles becomes high.

Early years[edit] In the early years, from until , all stamps were issued imperforate, and had to be cut from the sheet with scissors or knife. This was time-consuming and error-prone as mangled stamps of the era attest. Once reliable separation equipment became available, nations switched rapidly. Imperforate stamps have been issued occasionally since then, either because separation equipment was temporarily unavailable in newborn nations for instance , to makers of automatic stamp vending equipment the United States did this in the s and s , as novelties for stamp collectors particularly when stamps are issued in souvenir sheets , or as errors. Henry Archer[edit] In , Henry Archer constructed the first rouletting machine, the "Archer Roulette", to separate stamps. Two such machines were built. After experimentation both machines proved to be failures. From one machine a few stamps from Plates 70 and 71 have survived. This machine consisted of lancet-shaped blades working on a fly-press principle and piercing the paper with a series of cuts. Archer then abandoned this approach in favour of perforation, a process which used rows of small round pins to punch out the holes. In Archer patented his perforation machine which worked on the "stroke" principle. The arrangement of the pins enabled the top and sides of each stamp across the row to be perforated in a single operation, and this became known as "comb" perforation. Perforation trials were conducted in and under the auspices of the British Government and stamps from these trials were first issued towards the end of The Archer machine proved the viability of the process but never entered service. The Bemrose machine was designed as a rouletting machine. As such, it proved impracticable for stamp separation but in was successfully converted to a perforating machine by George C. Howard of Toppan Carpenter, stamp printers for the American Government. The key decision for the perforator is the spacing of the holes; if too far apart, the stamps will not separate easily, and the stamps are likely to tear, but if too close, the stamps will tend to come apart in normal handling. In a few cases the size of the holes has been a factor. Measurement and variations[edit] The standard for describing perforation is the number of holes or the "teeth" or perms of an individual stamp in a 2-centimeter span. The finest gauge ever used is 18 on stamps of the Malay States in the early s, and the coarsest is 2, seen on the stamps of Bhopal. Modern stamp perforations tend to range from 11 to Stamps that are perforated on one pair of opposite sides and imperforate on the other have most often been produced in coils instead of sheets, but they can sometimes come from booklet panes. Booklet panes can be associated with any combination of one, two or three imperforate sides. Sheet edges can produce any one imperforate side or two adjacent imperforate sides when the stamp comes from the corner of the sheet. Variations include syncopated perforations which are uneven, either skipping a hole or by making some holes larger. In the s, Great Britain began adding large elliptical holes to the perforations on each side, as an anti-counterfeiting measure. Rouletting[edit] Rouletting uses small cuts in the paper instead of holes. It was used by a number of countries, but was rarely if ever seen on modern stamps until the die-cut serpentine roulette self-adhesive varieties appeared. These are inevitably diecut, meaning that the stamps themselves are cut entirely apart, held together only by the backing paper. At first the backing paper was itself solid, but in a repeat of history, is now slightly rouletted so as to facilitate tearing off blocks of stamps without having to remove them from the backing. Since the diecut goes all the way through the stamp, any shape will work, and the original self-adhesives were straight-edged. However, the tradition of perforation is so strong that more recent self-adhesives have a wavy diecut simulating the perforation. It can be recognized by studying the edge of the stamp closely; true perforations will have torn paper fibers on each tooth, while simulated perforations are smooth. From to the United States also sold small numbers of the stamps issued during this period in sheets without die cuts, thus creating imperforated varieties of them. Their issuance was very controversial. Short or "nibbed" perms are undesirable and reduce value, as are bent or creased perms. Errors[edit] As is inevitable for a mechanical process like perforation, many things can go wrong. Blind perms are common, occurring when a hole is not completely punched out, as are off-center perms that cut into the design of the stamp, sometimes very badly. Occasionally pairs or larger groups of

stamps may be imperforate between meaning that they are not separated on all sides. Although it is very common to have different gauges of perforation horizontally and vertically, in rare circumstances a stamp may have different perforations on opposite sides; in the case of US stamps only a handful of these are known to exist. The various types of perforation errors are collectively known as misperfs.

Large Crown two types With only one exception, there were two watermarks used for ALL the perforated line engraved British stamps. They are both shown above. The various plates used to produce the line engraved 1 P. They are illustrated below. Die 1 Die 2 In the Die 2 stamps, the lines of the features are deeper and stronger. The fillet behind the ear is more distinct. The shading about the eye is heavier. The line of the nostril turned downward at the right, and an indentation of color appears between the lower lip and the chin. The transitional period from to is VERY confusing. I have tried to present these, as listed in the Scott Catalog, but in the major groups that are presented in the Gibbons Catalog. Therefore, each of the stamps pictured below may have more than one listing in the catalog table below its description. In some cases, it has been most difficult to match the exact catalog numbers from the two very different catalogs that I have used for reference. The first government perforated line engraved British stamps, shown above, were issued during and These stamps were perforated 16, and they were printed on various degrees of bluish paper that had WMK 18 -- the Small Crown watermark. Plate 4 and Plate 5 of the 2 P. The three stamps shown above were all issued in Their attributes are identical to those of the previous group, except that these stamps are perforated The two perforated line engraved British stamps, shown above, were also issued during These stamps were perforated 16, and they were printed on various degrees of bluish paper that had WMK the Large Crown watermark. The two stamps shown above were all issued in The two perforated line engraved British stamps, shown above, were issued in and These stamps were perforated 16, and they were printed on paper with WMK the Large Crown watermark. Some major changes were made to the line engraved British stamps, beginning in Instead of having stars in the upper corners and check letters in the lower corners, the new stamps have check letters in all four corners. The check letters in the lower corners are still the ones used to determine the stamps plate position, with the check letters in the upper corners being the same two letters but in reverse order of those in the bottom corners. The plate numbers, on each of the following British stamps, are located in the lattice work on either side of the vignette. This can be of tremendous help, when trying to locate varieties that occur on particular plates. The two new 2 P. They come in two types: Type I - Thick lines above and below head. From Plates , Type II - Thinner lines above and below head. However the two stamps above were issued 10 years apart. Here is the story. The rate change, however, never occurred. Most of the 10, sheets of these stamps that were printed were destroyed in Very few of these stamps have survived. The stamps were re-issued in and in a new color, shown at the right. The re-issued stamps are common. The new 1 P. Production continued through Plates 69, 70, 75, 77, , and were rejected, and no stamps exist for all but one of them. A few stamps from Plate 77 did reach the public, and they are all tremendously rare today. Here is a fun collecting idea for collecting this relatively inexpensive British stamp! Many collectors try to get an example of this stamp from each of the plates used during its production! Since the plate numbers are printed at the sides of each stamp, getting one of each plate number should take little more than a LOT OF perseverance. This stamp was issued on October 1, , and it was printed on paper with a script "half penny" watermark. The contemporary line engraved stamp denominations were then replaced by new surface printed British stamps of the same denominations.
